Abstract

Central ossifying fibroma is a rare benign fibro-osseous neoplasm which has a predilection for mandible. It originates from the mesenchymal blast cells of the periodontal ligament and has the capacity to produce bone, cementum, and fibrous tissue. It is a well-defined lesion primarily made of fibrous tissue, with small bits of bone, cementum, or tissue that looks like osteocementum. It is commonly seen in young adults with a female predilection. Herewith, we report a rare case of central ossifying fibroma affecting the right maxilla involving the maxillary sinus in a 73-year-old male patient.
